Aldo Gardini Statistics in the Al era: Obsolete discipline or essential tool?

- Data is a crucial resource in the modern era.
- Analyzing data is a highly sought-after task, involving professionals from various backgrounds such as engineers, computer scientists, mathematicians, physicists, and *sometimes* statisticians.
- The term data science often refers to a set of tools used for empirical analysis.
- While significant attention is given to methods, the overall workflow and some key aspects of an analysis are frequently guided by **common sense** and **intuition**.

 Starting point
 Starting

"To consult the statistician after an experiment is finished is often merely to ask him to conduct a post-mortem examination. He can perhaps say what the experiment died of."

Ronald Fisher (1890-1962). Creator of modern statistics.

The outcomes of a statistical analysis can include:

- Prediction or supervised classification.
- Dimensionality reduction.
- Exploring relationships among variables.

Aldo Gardini

・ロト ・ 日 ・ ・ ヨ ・

4 E

The outcomes of a statistical analysis can include:

- Prediction or supervised classification.
- Dimensionality reduction.
- Exploring relationships among variables.

A proper statistical analysis requires:

- Data.
- Understanding of the framework that generated the data.
- Knowledge of how to obtain meaningful results.
- Awareness of the limitations associated with the available data.

- Demonstrate how the mantra "Let the data speak for themselves" can fail dramatically in certain settings.
- Raise awareness that **analyzing data** involves more than just running code and interpreting results; it requires a comprehensive understanding of the relevant frameworks.
- To this end, we will explore four situations where intuition alone is insufficient for a proper analysis, leading to possible misleading conclusions.

Đ	Age < 80	81,396	136,684
_	${\sf Age} \ge 80$	9,132	3.154

Considering people < 80

- $Odds_{V|<80} = 2.5431 \times 10^{-3}$
- $Odds_{\bar{V}|<80} = 3.2191 \times 10^{-3}$

Association: $OR_{<80} = 0.7900$

Considering people \geq 80

- $Odds_{V|\geq 80} = 69.0977 \times 10^{-3}$
- $Odds_{\bar{V}|\geq 80} = 126.5060 \times 10^{-3}$

Association: $OR_{\geq 80} = 0.5462$

Statistics in the Al era: Obsolete discipline or essential tool?

-

- From a *formal* statistical perspective, both marginal and conditional analyses are correct.
- Incorporating knowledge about the phenomenon is necessary to achieve a causal interpretation of the problem.

This situation exemplifies **Simpson's paradox** (Simpson, 1951), where the direction of an association changes when moving from marginal to conditional analyses.

4 E

- From a *formal* statistical perspective, both marginal and conditional analyses are correct.
- Incorporating knowledge about the phenomenon is necessary to achieve a causal interpretation of the problem.

This situation exemplifies **Simpson's paradox** (Simpson, 1951), where the direction of an association changes when moving from marginal to conditional analyses.

More formally:

"Good for men, good for women yet bad for people"

It is a paradox only if the causal structure of the problem is ignored:

University of Bologna

- Expensive approach: Randomization. Although it requires significant time and resources, designing a randomized study effectively controls for confounding variables.
- Alternative approach: When only observational data are available, controlling for confounding necessitates specialized statistical methods that depend on a deep understanding of the causal diagram. Various methods are available to adjust for confounding in such cases.

Abstract

A preliminary observation of high frequency of male pattern hair loss among admitted COVID-19 patients and suggest that androgen expression might be a clue to COVID-19 severity.

Low incidence of daily active tobacco smoking in patients with symptomatic COVID-19 Preprint v3

Makoto Miyara¹⁽⁰⁾, Florence Tubach¹⁽⁰⁾, Valérie Pourcher¹⁽⁰⁾, Capucine Morelot-Panzini¹⁽⁰⁾, Julie Pernet¹, Julien Haroche¹, Said Lebbah¹, Elise Morawiec⁽⁰⁾, Guy Gorochov²⁽⁰⁾, Eric Caumes¹, Pierre Hausfater¹⁽⁰⁾, Alain Combes¹⁽⁰⁾, Thomas Similowski⁽⁰⁾, Zahir Amoura¹

Affiliations ~ Highly-cited researchers

Participants: We estimated the rates of daily current smokers in COVID-19-infected patients in a large French university hospital between February 28th, 2020 and March 30th, 2020 for outpatients and from March 23rd, till April 9th, 2020 for inpatients. Design: The rates from both groups were compared to those of daily current smokers in the 2018 French general population, established in 2018, after standardization of the data for sex and age.

Conclusions and relevance: Our cross sectional study in both COVID-19 out- and inpatients strongly suggests that daily smokers have a very much lower probability of developing symptomatic or severe SARS-CoV-2 infection as compared to the general population.

Aldo Gardini

Statistics in the Al era: Obsolete discipline or essential tool?

18 / 41

Almost all studies on Covid-19 rely on **non-random samples**. This is often overlooked when selecting methods and interpreting results.

The problem of collider bias is closely related to **sample collection methods** and is far more subtle than confounding!

For example, selection bias frequently occurs in:

- Observational studies,
- Voluntary sampling.

Collider bias occurs when the collider variable controls the sampling process. In our case, being in the sample means **being tested**!

Aldo Gardini

Statistics in the Al era: Obsolete discipline or essential tool?

Situation 1: late pandemic phase (Tattan-Birch et al., 2021)

??? = Cough!

Cough represented a symptom that increased the probability of being tested. Smokers are more subjected to cough, so they are **over-represented** in the sample, with a large number of negative tests.

Situation 2: early pandemic phase (Fenton, 2020)

- Swab tests performed on people with severe illness or healthcare workers.
- Healthcare workers subjected to higher viral load. High probability of severe illness.
- Healthcare workers tend to smoke less than the remaining population.

イロト イヨト イヨト イヨト

Aldo Gardini

Statistics in the Al era: Obsolete discipline or essential tool?

- Utilize conditional (network) models that are based on causal schemes developed by researchers.
- Examine the composition of the available sample (e.g., demographic or socio-economic status). If systematic discrepancies are observed with respect to the target population, apply post-stratification procedures.
- Again, randomization!

A simple res	earch questior	l				

Problem from Lord (1967)

A university is interested in investigating the effects on the students of the diet provided in the university dining halls and any sex difference in these effects.

For each student we know:

- Weight at the time of arrival (W_I)
 Weight at June (W_F)
 Gain: Y = W_F W_I
- Sex (*S*)

Aldo Gardini

How would you exploit the data to answer the guestion?

You consider the gain Y and you simply test for differences in mean in the two sub-populations individuated by sex S.

Basic statistical tool: t-test (equivalent to ANOVA when 2 groups are present).

Results:

	mean(Y)	SD(Y)
Male	0.043	0.174
Female	0.039	0.171

p-value: 0.869

No significant differences in the gain comparing the two groups.

イロト イヨト イヨト イヨト

Aldo Gardini

Statistics in the Al era: Obsolete discipline or essential tool?

You compare the gain in the two sub-populations individuated by S, considering the initial weight W_l .

Still a basic statistical tool: ANCOVA, i.e. analysis of covariance.

Result:

In average, a male have a gain higher of 0.447 than a female, keeping constant the initial weight (significant difference with p-value $< 10^{-16}$).

27 / 41

Aldo Gardini

Statistics in the Al era: Obsolete discipline or essential tool?

As pointed out by Pearl (2016), again the solution is in the causal structure of the phenomenon!

▲□▶ ▲□▶ ▲臣▶ ▲臣▶ = 臣 = のへの

Aldo Gardini Statistics in the Al era: Obsolete discipline or essential tool?

As pointed out by Pearl (2016), again the solution is in the causal structure of the phenomenon!

Solution 1. It evaluates the **total effect** of S on Y:

$$TE = b + ac - a$$
.

Solution 2. It evaluates the direct effect of S on Y, considering W_I as mediator effect:

DE = b.

Empirical ex	periment					

• An experiment produced n = 11 observations of two numerical variables X and Y, with the following descriptive statistics.

	Mean	S.D.
X	9.00	3.32
Y	7.50	2.03

• A simple linear model is fitted:

$$y_i = \beta_0 + \beta_1 x_i + \varepsilon_i; \quad \varepsilon_i \stackrel{ind}{\sim} \mathcal{N}(0, \sigma^2), \ \forall i.$$

• The following outcomes are observed

$$\hat{\beta}_0 = 3.00, \quad \hat{\beta}_1 = 0.50, \quad R^2 = 0.67.$$

How to deal with this?						

When applying a statistical model (or test) to data, certain assumptions are implicitly made and must be **carefully assessed**.

In our example, we consider a linear model with two variables, where simple scatter plots can provide valuable insights.

33 / 41

Graphical inspection of residuals can be highly informative! Being defined as

$$\hat{e}_i = y - \beta_0 - \beta_1 x_i - (\beta_2 x_{2i} + \cdots),$$

they are valid also when multiple regressors are included.

Through 4 basic plots, we can verify:

- Homoscedasticity
- Presence of non-linear relationships
- Presence of outliers
- Departures from Normality assumption

So, is statis	tics still usefu	?				

- Statistics offers a set of **tools** for analysing data, nowadays largely used (and also developed) by non-statisticians.
- The diffusion of such methods (and their user-friendliness) is not supported by the diffusion of statistical culture. The discipline is not appealing!
- Anyone can use statistics, without being a statistician.
